A METHOD FOR PROCESSING TEST SCORES WITH MINIMAL PUNCHED CARD EQUIPMENT

Frank G. Benham Manatee County*

With the installation of a set of IBM Series 50 punch card machines in the Manatee County Schools, it was decided that the machines should be utilized for processing test data wherever possible. The current installation consists of a sorter, key punch, and an accounting machine, which represent a minimal installation. This paper will describe the processing of an achievement test battery with maximum use of the available equipment. In addition to the above listed equipment, an IBM 805 test scoring machine was available.

In previous years the achievement tests were administered by the teachers and scored by machine in the county office. They were then returned to the teachers who converted the raw scores to grade placement scores and made class lists. With the present method the answer sheets are scored in the county office, the raw scores are converted by machine to grade placement scores, and a class list is returned to the teachers. The succeeding sections will detail the processing and suggest other applications using the same basic material.

IBM machine scoring answer sheets for the California Achievement Tests were scored in the usual mannerwith the 805 test scoring machine. During the administration of the test the teachers had instructed the pupils to place a three digit identification number on each answer sheet. This number indicated grade level and teacher. After scoring, the answer sheets were arranged into alphabetical order by hand. An order of reading, arithmetic and language answer sheets was maintained for each child. Appendix A lists times required per hundred students for the major operations so that the reader may estimate costs by his own clerical pay scale.

A key punch operator made a card for each student with identification of school, the class room identification, child's name, and six raw scores representing the six subtests of the achievement battery. Appendix B contains a list of card column contents.

When a group of approximately 1,000 such pupil cards had been accumulated, they were sorted on the basis of a single subtest raw score. A master deck was sorted which contained all of the possible raw scores and their corresponding grade placement scores. The master deck was utilized to punch the grade placement scores automatically onto the pupil

data cards. This process is repeated six times to convert each raw score to a grade placement score.

The pupil data cards were then ordered alphabetically, by school, and home room. This ordering was done by machine sorting. After cards were ordered they were put through the accounting machine to produce a class list with pupil name and grade placement scores for the six subtests. Three additional columns were produced for each child on this run. The two reading grade placement scores were summed and the total printed. In a like manner a sum was printed for each child's arithmetic and language scores. This accounting machine run represents a work sheet from which a clerk in the county office hand calculated average grade placements for reacing, arithmetic, language, and the entire battery. Appendix C contains a sample of the work sheet.

After the averages were calculated, the work sheet was returned to the key punch operator who punched the averages in the child's original data card. A final run on the accounting machine produced class lists for the teachers, principals, elementary and secondary supervisors, and psychologist. Appendix D contains a sample of the final class list.

From the pupil data cards a frequency distribution is easily obtained in the accounting machine by sorting for a particular series of scores and using the card count device. During this same run the scores may be summed for computation of the mean.

With the data in a flexible form as provided by the use of individual pupil cards, many possibilities present themselves for increased use of the achievement test material. For example, Manatee County uses a spring testing program, and with class lists available to the principal during the summer, he is able to provide the following year's teachers with a complete set of achievement test scores for their new classes. These new class lists are available for pre-school orientation use.

ł

By sorting in terms of scores, lists may be provided to the principal to aid in forming classes grouped according to achievement level. Selection of students with extremely high or low scores for special attention may be quickly done by using the mechanical sorter and the accounting machine for listing.

It is the writer's opinion that from four to six hours of teacher time are saved by the machine processing system outlined in this paper. In addition, there is a considerable saving in time due to the automatic tabulation available for statistical process. It is believed that the achievement test material will be more accessible and in a more useable form, and that these factors will encourage wider use by teachers of the available data.

Appendix A

Time Required Per 100 Students for Major Operations Discussed in Text

| Operation | Time in Hours |
|--------------------------------------------------|---------------|
| Hand Order Answer Sheets | 1.00 |
| First Key Punch | . 83 |
| First Accounting Machine Run (Work Sheets) | .10 |
| Averaging | . 83 |
| Second Key Punch | . 25 |
| Second Accounting Machine Run (Final Class List) | .14 |
